Several epidemiological and experimental studies have demonstrated that exposure to arsenic is associated with vascular disease such as atherosclerosis. Since vessel proteoglycans (PGs) are key molecules in the progression of the vascular lesion, we investigated the effect of arsenic on the synthesis of PGs in cultured bovine aortic endothelial cells. The results indicate that sodium arsenite (NaAsO₂) significantly decreases the accumulation of both heparan sulfate PGs and chondroitin/dermatan sulfate PGs in the cell layer and the conditioned medium of the cells without nonspecific cell damage and inhibition of whole protein synthesis. While sodium arsenate (NaHAsO₄) did not influence PG synthesis, arsenic trioxide (As₂O₃) inhibited PG synthesis as a result of nonspecific cell damage. The present data suggest that arsenite may contribute to the progression of atherosclerosis through inhibition of PG synthesis in vascular endothelial cells.

Key words — arsenite, glycosaminoglycan, proteoglycan, vascular endothelial cell, atherosclerosis

INTRODUCTION

Proteoglycans (PGs) are a heterogeneous group of molecules that are prominent constituents of both the extracellular matrix and the cell surface and have the common structure of a core protein, to which one or more glycosaminoglycan (GAG) chains are covalently attached.¹ Vascular endothelial cells predominantly synthesize and secrete the large heparan sulfate PG (HSPG), perlecan,² and the small chondroitin/dermatan sulfate PG (CS/DSPG), biglycan.³ Vascular PGs are involved in the pathogenesis of vascular diseases as well as in the regulation of arterial properties such as vascular permeability, lipid metabolism, hemostasis, thrombosis, and extracellular matrix assembly.⁴–⁷ In addition, PGs influence the regulation of vascular endothelial and smooth muscle cell functions by modulating growth factor availability and function.⁸–¹⁰

Atherosclerosis is a vascular lesion which is initiated by functional damage in vascular endothelial cells followed by vascular smooth muscle cell hypertrophy in the intima of the vascular wall.¹¹ We have previously shown that the environmental pollutants lead and cadmium, which have been shown to induce atherosclerosis,¹²,¹³ exhibit specific toxicity in vascular endothelial and smooth muscle cell functions such as the proliferation, fibrinolysis, and extracellular matrix formation.¹⁴ In addition, we found that the lead-induced inhibitory effect on endothelial cell proliferation is due to a lower response of the cells to endogenous fibroblast growth factor-2 (FGF-2) caused by suppression of perlecan synthesis in the cells.¹⁵ Cadmium also perturbs the synthesis of PGs in vascular endothelial¹⁶,¹⁷ and smooth muscle cells.¹⁸ Based on these findings, we have proposed that the mechanisms underlying vascular toxicity of heavy metals involve abnormal PG metabolism in vascular cells.¹⁹

Epidemiological studies have shown that arsenic as well as cadmium and lead is a possible risk factor for vascular disease related to atherosclerosis. In the United States, it has been reported that there is a correlation between standard mortality ratios for cardiovascular disease and arsenic levels in drinking water.²⁰,²¹ In addition, exposure to arsenic in arsétesian well water is associated with “Blackfoot disease”²² and with increased mortality from cardiovascular cerebrovascular disease.²³–²⁰ The inorganic pentavalent form of arsenic (arsenate) is the predomi-
nent type of arsenic found in drinking water. Arsenic is reduced to the trivalent form (arsenite) in vivo, which can be further metabolized to mono- and dimethylated derivatives.\textsuperscript{27} Among inorganic arsenics, arsenite is in general the most toxic form.\textsuperscript{28} It is likely that the cellular mechanisms and regulatory pathways for vascular disease in response to arsenite may involve dysfunction of vascular cells, including inflammatory, coagulating activity and impairs nitric oxide homeostasis.\textsuperscript{29}

Arsenite accelerates atherosclerosis in apolipoprotein E-deficient mice, a model of human atherosclerosis.\textsuperscript{30,31} We hypothesized that arsenite perturbs the regulation of PG synthesis in vascular cells during the progression of atherosclerosis. In the present study, we investigated the synthesis of PGs in cultured bovine aortic endothelial cells after exposure to sodium arsenite. It was found that sodium arsenite suppresses the synthesis of both HSPGs and CS/DSPGs in the cells.

**MATERIALS AND METHODS**

**Materials** — Vascular endothelial cells derived from bovine aorta were purchased from Dainippon Pharmaceutical (Osaka, Japan). Dulbecco’s modified Eagle’s medium (DMEM) and ASF 301 medium were obtained from Nissui Pharmaceutical (Tokyo, Japan) and Ajinomoto (Tokyo, Japan), respectively. Tissue culture dishes and plates were from Iwaki (Chiba, Japan). $^{[35S]}$Na$_2$SO$_4$ (carrier-free) and fetal bovine serum were from MP Biomedicals (Irvine, CA, U.S.A.). [4,5-$^3$H]Leucine (4.44 TBq/mmol) was purchased from Moravek Biomedicals (Brea, CA, U.S.A.). Sodium arsenite (NaAsO$_2$), arsenic trioxide (As$_2$O$_3$), sodium arsenate (Na$_2$HAsO$_4$), DEAE-Sephasel, benzamidine, Tris base and phenylmetanesulfonyl fluoride were purchased from Sigma-Aldrich (St. Louis, MO, U.S.A.). The lactate dehydrogenase (LDH) kit and urea were purchased from Bioassay Systems (Hayward, CA, U.S.A.). Cetylpyridinium chloride (CPC) and other reagents were obtained from Nacalai Tesque (Kyoto, Japan).

**Morphological Examination** — Vascular endothelial cells were cultured in DMEM supplemented with 10% fetal bovine serum in 100 mm dishes at 37°C in a humid atmosphere of 5% CO$_2$ in air until confluence. They were then transferred into 24-well culture plates and cultured until confluence in DMEM supplemented with 10% fetal bovine serum. The medium was discarded and the cell layer was washed twice with serum-free ASF 301 medium. The cell layer was then incubated at 37°C for 48 hr in fresh serum-free ASF 301 medium with sodium arsenite (0.1, 0.2, 0.5, 1 or 2 µM). After incubation, the medium was discarded and the cell layer was washed with Ca$^{2+}$, Mg$^{2+}$-free phosphate-buffered saline (CMF-PBS), fixed with methanol, and stained with Giemsa.

**Incorporation of $[^{35S}]$Sulfate into GAGs** — The incorporation of $[^{35S}]$sulfate into GAGs was determined by the CPC precipitation method.\textsuperscript{32} Briefly, aliquots of the medium and cell extracts were spotted on filter papers and washed five times for 1 hr in 1% CPC with 0.05 M NaCl. The radioactivity of precipitated proteoglycans on the dried filter paper was measured by liquid scintillation counting.

**Characterization of PGs** — To separate PGs on the basis of differences in charge density, the macromolecules were applied to DEAE-Sephasel (5 ml of resin) in 8 M urea buffer (pH 7.5) containing 2 mM EDTA, 0.1 M NaCl, 0.5% Triton X-100 and 50 mM Tris base to obtain high molecular mass (> 3 kDa) macromolecules.
48 hr in 0.25 ml of fresh serum-free ASF 301 medium with sodium arsenite (0.1, 0.2, 0.5, 1 or 2 µM), arsenic trioxide (2 µM) or sodium arsenate (2 µM). After incubation, the conditioned medium was harvested and an aliquot of the medium was used for the assay of LDH activity, an indicator of cell death.

**Protein Synthesis** —— Confluent cultures of vascular endothelial cells in 6-well culture plates were incubated at 37°C for 48 hr in the presence of sodium arsenite (0.1, 0.2, 0.5, 1 or 2 µM) in 1 ml of serum-free ASF 301 medium and labeled with [3H]leucine (50 kBq/ml) during the last 3 hr of incubation. After incubation, the medium was discarded and the cells were washed twice with ice-cold CMF-PBS; the cells were scraped off with a rubber policeman in the presence of 0.75 ml CMF-PBS. The culture well was washed with 0.75 ml CMF-PBS and the wash was combined with the cell suspension. The cell homogenate was prepared by sonication and the incorporation of [3H]leucine into the 5% trichloroacetic acid-insoluble fraction of the cell homogenate was determined by liquid scintillation counting. A portion of the cell homogenate was used for the determination of DNA content by a fluorometric method33) to express the incorporated radioactivity as dpm/µg DNA.

**Statistical Analysis** —— Data were analyzed for statistical significance by analysis of variance (ANOVA) and Bonferroni’s multiple t-test. p-Values of less than 0.05 were considered to indicate statistically significant differences.

**RESULTS**

Figure 1 shows the morphological appearance of cultured vascular endothelial cells after exposure to sodium arsenite at 2 µM or less for 48 hr. Neither a decrease in cell number nor degenerative change was observed in the cells even after treatment with sodium arsenite, suggesting that sodium arsenite does not exhibit cytotoxicity to vascular endothelial cells.

Figure 2 shows the accumulation of [35S]sulfate-PGs in the cell layer and the conditioned medium of vascular endothelial cells after exposure to sodium arsenite. After a 48-hr incubation, sodium arsenite at 0.5 µM and more significantly decreased the PG accumulation in both the cell layer and the conditioned medium. The decrease in the PG accumulation by sodium arsenite at 2 µM occurred after 24 hr and longer in the cell layer and after 48 hr in the conditioned medium. These results suggest that sodium arsenite inhibits the synthesis of PGs in vascular endothelial cells, although the inhibitory effect is not marked.

The [35S]sulfate-labeled PGs were submitted to a DEAE-Sephacel column to separate the PGs into HSPGs and CS/DSPGs based on charge density differences (Fig. 3). In the cell layer, either with or without sodium arsenite treatment, the incorporated [35S]sulfate radioactivity eluted from the column by the NaCl gradient in two peaks, at approximately 0.4 and 0.5 M; these two peaks have been previously confirmed to contain HSPGs and CS/DSPGs34,35), respectively. It was revealed that sodium arsenite significantly decreased the radioactivity of both HSPGs and CS/DSPGs (80 and 54%, respectively, of the control). In the conditioned medium, PGs were also eluted by NaCl at approximately 0.4 and 0.5 M; sodium arsenite decreased the radioactivities of HSPGs and CS/DSPGs (85 and 92%, respectively, of the control). These results indicate that sodium arsenite inhibits the synthesis of both HSPGs and CS/DSPGs in vascular endothelial cells.

Table 1 shows the incorporation of [3H]leucine into the acid-insoluble fraction and the leakage of lactate dehydrogenase in vascular endothelial cells treated with sodium arsenite at 2 µM or less for 48 hr. It was shown that sodium arsenite did not change
the [3H]leucine incorporation and increased the LDH leakage, suggesting that sodium arsenite-induced inhibition of endothelial PG synthesis was due to neither inhibition of whole protein synthesis nor nonspecific cell damage. The effects of sodium arsenite, arsenic trioxide, another trivalent arsenic compound, and sodium arsenate on endothelial PG synthesis were compared (Table 2). After a 48-hr incubation, arsenic trioxide as well as sodium arsenite, significantly decreased the accumulation of [35S]sulfate-labeled PGs in both the cell layer and the conditioned medium, suggesting that arsenic trioxide also inhibits PG synthesis in vascular endothelial cells. However, arsenic trioxide significantly increased the activity of LDH that had leaked into the conditioned medium from the cells, indicating that arsenic trioxide-induced inhibition of endothelial PG synthesis results from nonspecific cell damage. On the other hand, sodium arsenate did not influence either PG synthesis or the LDH leakage.

Fig. 2. Incorporation of [35S]Sulfate (A) and Time Course of the Incorporation (B and C) into GAGs Accumulated in the Cell Layer and the Conditioned Medium of Vascular Endothelial Cells after Exposure to Sodium Arsenite

Confluent cultures of bovine aortic endothelial cells were incubated at 37°C for 48 hr with sodium arsenite (0.1, 0.2, 0.5, 1 or 2 µM) (A) or incubated at 37°C for 8, 24 or 48 hr with sodium arsenite (2 µM) (B and C) in the presence of [35S]sulfate. Values are means ± S.E. of four samples. Significantly different from the corresponding control, *p < 0.05; **p < 0.01.

Fig. 3. DEAE-Sephacel Ion Exchange Chromatography of [35S]Sulfate-Labeled PGs Extracted from the Cell Layer and the Conditioned Medium of Vascular Endothelial Cells after Exposure to Sodium Arsenite with a Linear Gradient of 0.25–0.7 M NaCl in 8 M Urea Buffer

Confluent cultures of bovine aortic endothelial cells were incubated at 37°C for 48 hr with sodium arsenite (2 µM) in the presence of [35S]sulfate.
DISCUSSION

In the present study, it was shown that sodium arsenite significantly inhibits PG synthesis in vascular endothelial cells without nonspecific cell damage. Although the synthesis of both HSPGs and CS/DSPGs was inhibited, the inhibition was not due to suppression of whole protein synthesis. In contrast, sodium arsenate did not show such an inhibitory effect, and arsenic trioxide decreased PG synthesis with exhibiting cytotoxicity. These results indicate that the effect of arsenic on endothelial PG synthesis is different among the chemical forms.

Sodium arsenite decreased the accumulation of HSPGs in the cell layer and the conditioned medium to a similar degree (80 and 85%, respectively, of the control). On the other hand, the accumulation of CS/DSPGs in the cell layer was 54%, while that in the conditioned medium was 92% after treatment with sodium arsenite, suggesting that sodium arsenite inhibits not only the synthesis of both HSPGs and CS/DSPGs but also disturbs the association of CS/DSPGs to the cell layer. As the result, inhibition of the accumulation of PGs in the cell layer may occur earlier than that in the conditioned medium.

There is a strong interrelationship between atherosclerosis and thrombosis. Vascular endothelial cells have anticoagulant and fibrinolytic properties that contribute to the prevention of vascular lesions such as atherosclerosis. Arsenite inhibits tissue-type plasminogen activator synthesis with induction of plasminogen activator inhibitor-1 synthesis in cultured human microvascular endothelial cells, resulting in a lower fibrinolytic activity of the cells. The major PGs synthesized by vascular endothelial cells are perlecan and biglycan, which exhibit antithrombin activity through activation of antithrombin and heparin cofactor II, respectively. Thus, arsenite may contribute to thrombosis in atherosclerosis by the reduction of endothelial PG synthesis.

as well as the reduction of endothelial fibrinolytic activity.

When vascular endothelium is injured, FGF-2 leaks from the damaged endothelial cells and the growth factor then promotes repair of the damaged endothelium via stimulation of proliferation and migration of the cells near the damaged site in an autocrine fashion. Perlecan markedly promotes the binding of FGF-2 to its cell surface receptor. We have previously demonstrated that lead inhibits the repair of wounded endothelial cell layers, which result from a lower response to endogenous FGF-2 caused by inhibition of perlecan synthesis in the cells. It is likely that arsenite may inhibit the repair process of endothelium as does lead, although it does not injure the endothelial monolayers. In fact, arsenite stimulates the growth of cultured vascular endothelial cells after confluence but inhibits the log-phase growth of the cells.

It was reported that vascular disease, such as Blackfoot’s disease, occurred around well waters containing between 4.8 and 15.6 µM arsenite in areas of Taiwan. The human blood concentration of arsenite is three to nine times lower than the environmentally relevant level of arsenite in drinking water. These results suggest that the blood concentration of arsenite can be between approximately 0.5 and 5 µM. In addition, epidemiologically, chronic exposure to arsenite at concentrations exceeding 0.25 µM in drinking water is associated with increased mortality from cardiovascular disease. In the present study, it was shown that sodium arsenite at concentrations of 0.5 µM and more inhibited the synthesis of PGs in vascular endothelial cells. Therefore, it is suggested that inhibition of endothelial PG synthesis by arsenite can contribute to vascular diseases such as atherosclerosis in human beings.

In conclusion, the present data demonstrate the inhibitory effect of sodium arsenite on the synthesis of HSPGs and CS/DSPGs in vascular endothelial cells. The inhibition of endothelial cell PG synthesis by arsenite may contribute to the progression of atherosclerosis through reduction of the endothelial anticoagulant activity and the ability of the cells to respond to FGF-2 during the repair of damaged endothelium.
