Shou-Wu-Pian, a herbal remedy formulated from *Polygonum multiflorum* (PM), has been extensively used for the treatment of hair-loss, constipation and vertigo in Asia, Europe and U.S.A. Although recent reports have indicated severe liver damage occurred after taking Shou-Wu-Pian in humans, studies on the hepatotoxicity of this herbal remedy have been limited, and this organ-specific adverse effect induced by PM intake remains to be confirmed. In this study, hepatotoxicity of hot-water-extracted PM was investigated *in vitro* and *in vivo* in mice. After treating primary cultured hepatocytes with PM extracts at 3 final concentrations (0.5, 1 and 5 mg/ml) with or without acetaminophen (10 mM) for 24 hr, no cytotoxic effects were observed. In fact, cell viability and lactate dehydrogenase leakage were significantly improved at the highest PM extracts dose compared with controls. Mice orally administered twice daily with the PM extracts (20 or 340 mg extracts/mouse × 2) for 10 days indicated no unfavorable effect on the liver function. Only when mice subchronically received the higher dose of the PM extracts (340 mg) before treatment with a single-bolus dose of acetaminophen (500 mg/kg; i.p.), attenuation of acetaminophen-induced hepatotoxicity was significantly established *in vivo*. The results in the present study contradicted hepatotoxic findings reported in humans; PM extracts do not induce any toxicological effects, at least on the liver, and may in fact elicit useful but limited beneficial effects on the liver *in vivo*.

Key words —— *Polygonum multiflorum*, herbal medicine, hepatocyte, acetaminophen, lactate dehydrogenase

INTRODUCTION

There is growing evidence that herbal medicines have multiple beneficial effects on human health maintenance. As a result of growing distrust in chemically synthesized compounds (modern therapeutics/medicines) and “on-line shops” on the internet, patients are taking note of alternative medicines/remedy and herbal products. Taking traditional Chinese medicines has always been perceived to be a safe remedy merely because these preparations are accepted as “natural products.” However, reports of adverse reactions elicited by these so-called “natural products” have been increasing since the 1990s.1–7) In 2001, a woman who took a herbal medicine/product derived from *Polygonum multiflorum* (PM) showed acute hepatitis-like symptoms with marked increases of serum alanine aminotransferase (ALT) to as high as 900 U/l.1) More recently, 2 cases with hepatotoxicity supposedly caused by taking PM products have been documented.3) As a consequence, caution on the intake of PM preparations have been heeded in “herbal safety news and food safety information” by the British and Japanese governments in April8) and May9) of 2006, respectively. However, hepatotoxic effects of the herbal product remain unclear as experimental and clinical studies with regulated and strict controls have not been attempted to date. In contrast to these unfavorable reports on humans, PM extracts have been reported to elicit various beneficial effects in experimental animals,10–13) viz., the extracts promote hair growth in the hair-loss mouse model,10) ameliorates behavioral abnormalities and biochemical parameters in the experimen-
tal Alzheimer’s disease model (induced by amyloid β-treatment) and attenuates carbon tetrachloride (CCl₄)-induced liver dysfunction.

PM extracts may serve as a useful ingredient in herbal products, and it contains multivariate pharmacologically active principles, such as polyphenolic compounds, minerals and other organic/inorganic components. Although useful, variations in the content of these pharmacologically active components yield complications and repercussions in the evaluation of herbal medicines incorporating PM extracts. Thus, elaborate in vitro and in vivo experiments are warranted to evaluate toxic and beneficial effects of PM extract-incorporated herbal medicines. As direct in vitro and in vivo effects on hepatocytes and the intact liver have not been respectively attempted, we therefore elucidated the effects of hot-water PM extracts on hepatic functions using primary-cultured hepatocytes in vitro and the acetaminophen-induced liver injury model in vivo in mice.

MATERIALS AND METHODS

Animals —— Male ICR mice (age: 7 to 10 weeks, body weight: 25–35 g; SLC, Shizuoka, Japan) accommodated in an air-conditioned room under an alternating 12-hr light-dark illumination cycle were given feed and drinking water ad libitum. Experimental studies were conducted according to the “Guidelines for care and use of laboratory animals” stipulated by the Ethical Committee of Asahikawa Medical College.

Reagents —— PM (Tochimoto Tenkaido Co. Ltd., Osaka, Japan), William’s medium E, fetal calf serum (FCS), L-glutamine (GIBCO, Carlsbad, CA, U.S.A.), fetal bovine serum (Tissue Culture Biologicals, Tulare, CA, U.S.A.), collagenase type II (Worthington Biochemical Co., Lakewood, NJ, U.S.A.), acetaminophen, penicillin-streptomycin (Sigma, St. Louis, MO, U.S.A.) and other chemicals (Wako Pure Chemicals, Osaka, Japan) used in the experiments were either of the highest or analytical grade.

Preparation of PM Extracts —— PM (5 g or 85 g) was submerged in 300 ml of distilled water, and the mixture was boiled under reflux for ca. 2 hr until the water volume was concentrated to 50 ml (100 or 1700 mg/ml extracts, respectively). The concentrate (clear brown solution) was sterilized by PVDF-membrane filtration (pore size: 0.45 mm, Millipore, Billerica, MA, U.S.A.). The collected extracts were kept at 4°C and warmed up to 37°C just before use.

In vitro Study Using Isolated Murine Hepatocytes —— Isolated hepatocytes from male ICR mice were prepared by the collagenase perfusion method of Moldeus et al. with slight modifications. Briefly, the surgically exposed liver of the ketamine/xylazine-anesthetized mouse was initially perfused with Hank’s balanced solution (pH 7.4) supplemented with HEPES (10 mM) and NaHCO₃ (4.16 mM) for 20 min (total volume: 150 ml) followed by Hank’s balanced solution containing collagenase (321 units/ml) at a flow rate of 8 ml/min for 12 to 15 min (volume used: 100 ml). The isolated hepatocytes were washed twice with 20 ml of phosphate buffered saline (PBS, pH 7.2) before centrifugation at 50 × g at 4°C for 1 min. The hepatocytes were then suspended in William’s E medium containing 10% FCS (2 × 10⁵ cells/ml) before being seeded onto a collagen-coated 24- or 96-well plate at 1 × 10⁴ cells/cm². Isolated hepatocytes were cultured in William’s medium E containing 10% FCS, glutamine (2 mM), penicillin (100 U/ml) and streptomycin (0.1 mg/ml) at 37°C for 6 hr. The trypan blue exclusion test revealed hepatocyte viability to have surpassed 90%.

After rinsing, cells in the plates were treated with 3 different concentrations of the PM extracts (final concentrations: 0.5, 1 and 5 mg/ml extracts) with or without 10 mM acetaminophen for 24 hr in the culture medium containing 10% FCS or in the serum-free medium. Effects on the hepatocytes were monitored with the lactate dehydrogenase (LDH)-leakage into the culture medium from cells using the LDH-cytotoxic test (Wako Pure Chemicals), and cell viability was evaluated by the WST-8 test.

In vivo Effect of PM —— Mice were orally administered an aliquot of the PM extracts (lower dose: 20 mg/0.2 ml/mouse, higher dose: 340 mg/0.2 ml/mouse) twice a day (10:00 and 16:00 hr) with a stomach tube for 10 consecutive days. Control mice were treated in a similar manner with oral intake of distilled water (0.2 ml/intake) twice daily. Two hr after the final drug/vehicle administration on day 10, mice were intraperitoneally administered with acetaminophen (500 mg/kg; dissolved in saline). Blood was sampled and relevant organs (i.e., liver, spleen, thymus, kidney) were extracted from mice under ether anesthesia 4 hr after acetaminophen treatment. Plasma ALT, aspartate aminotransferase (AST), LDH and total bilirubin
(T-Bil) levels were determined using a commercial kit (Transaminase C II-test, Wako Pure Chemicals) or determined by SRL laboratories (Tokyo, Japan) for liver functions.

**Histopathological Study** —— After 12 hr of fixing in 4% paraformaldehyde solution, liver tissue embedded in paraffin was cut into 4 µm thick serial sections. The specimen was mounted on a glass slide and deparaffinized with graded concentrations of xylene and ethanol, and then stained with hematoxylin and eosin. The microscopic observation was examined under an Olympus BX50 microscope (Olympus, Tokyo, Japan).

**Statistical Analysis** —— All values expressed as the mean ± S.E. were statistically verified by the one-factorial analysis of variance (ANOVA) method before the post-hoc Tukey’s Multiple Comparison test. Differences where a p value of < 0.05 were considered statistically significant.

**RESULTS**

**Effects of the Hot-water PM Extracts on Cultured Murine Hepatocytes**

The amount of LDH leaked into the culture medium was designated as 100% when cells were treated with culture medium containing 1% Tween 20. Removal of serum from the culture medium resulted in cell damage; 20% LDH-leakage from the cell was subsequently observed (Fig. 1). From the *in vitro* findings based on LDH-leakage and cell viability (Figs. 1 and 2), the PM extracts did not induce any hepatotoxic effect in the primary cultured hepatocytes. On the contrary, pretreatment with the highest amount of PM extracts significantly (*p* < 0.01) reduced the basal level of LDH-leakage (Fig. 1).

**In vitro Effects of the PM Extracts on Acetaminophen-induced Hepatotoxicity**

Acetaminophen treatment induced significant (*p* < 0.001) hepatotoxicity (Fig. 1); i.e., LDH-leakage into the culture media was 60% and 20% of total intracellular contents in the acetaminophen-treated and control hepatocytes (Fig. 1). A similar cytotoxic tendency was observed in the cell viability assay, acetaminophen (10 mM) treatment markedly (*p* < 0.01) killed 50% of hepatocytes compared with non-treated cells (Fig. 2).

Interestingly, co-incubation of hepatocytes with the PM extracts attenuated acetaminophen-induced hepatotoxicity in a dose-dependent manner (Fig. 1). At the highest (5 mg/ml) dose, treatment with the PM extracts completely attenuated acetaminophen-induced LDH-leakage in hepatocytes (*p* < 0.01, Fig. 1) and significantly prevented acetaminophen-induced cell death (*p* < 0.01, Fig. 2).
**In vivo Evaluation of the PM Extracts on Acetaminophen-induced Acute Hepatotoxicity**

The subchronic PM treatment (both lower and higher doses) did not affect organ/tissue weights or hematological parameters (red blood cell/white blood cell and platelet counts, mean corpuscular volume, hemoglobin content, mean cell hemoglobin and mean corpuscular hemoglobin concentrations) in treated mice compared with those in controls (data not shown) as well as plasma markers of hepatic function (Fig. 3). The behavioral abnormality was not observed during and after the treatment with PM extracts. A single-bolus administration of acetaminophen (500 mg/kg)-induced acute hepatotoxicity assessed by plasma ALT, AST, LDH and T-Bil levels (Fig. 3). The 10-day consecutive pretreatment of the PM extracts attenuated the acetaminophen-induced hepatotoxicity, albeit the lower dose of PM extract did not show significant differences (Fig. 3).

Histopathological study revealed that the treatment with acetaminophen caused marked hepatic cell loss, especially around central veins, and erythrocyte leakage (Fig. 4 B). The pretreatment (10 days) of higher dosage of PM extract dramatically attenuated acetaminophen toxicity (Fig. 4 D), although the lower dosage was ineffective (Fig. 4 C).

### DISCUSSION

Several reports have described severe hepatic dysfunctions caused by the intake of PM products in humans;\(^1\text{—}^3\) however, *in vitro* and *in vivo* findings in the present study showed protective effects. As far as we know, this is the first study that has demonstrated the non-cytotoxic effects of PM extract on primary cultured hepatocytes when monitored by cell viability. Additionally, the subchronic (10-day) PM pretreatment (a daily dose: 40 or 380 mg/mouse) did not affect the hepatic function in mice when evaluated by plasma markers of hepatic function and other hematological parameters. A daily dose of 40 mg extract intake (ca., 1.3 g/kg) in a mouse equals 80 g PM extract intake per day for a 60-kg human individual, while the recommended daily dose of PM for humans is 3–6 g. These results provided essential important information for the consumers that the use of PM products within the recommended dose range could be potentially safe, at least for the liver, without any medical consultation with a physician, although consideration of the species difference in PM metabolism/response between humans and mice might have to be taken into account to a certain extent. The previously reported adverse events in humans\(^1\text{—}^3\) might have been due to possible contamination from other sources in

![Fig. 3. Effects of Sub-chronic Treatment with PM Extracts on Liver Function in Mice](image-url)

Mice were orally pretreated with hot-water-extracted PM (lower dose: 20 mg/0.2 ml/mouse, higher dose: 340 mg/0.2 ml/mouse) twice a day for 10 consecutive days, while control animals were similarly treated with distilled water (2 × 0.2 ml per day). On day (final) 10, acetaminophen (500 mg/kg) was injected intraperitoneally in mice 2 hr after the last oral administration of PM extract. Blood samples were drawn from ether-anesthetized mice by cardiac puncture 4 hr after acetaminophen injection. Plasma ALT (A), AST (B), LDH (C) and T-Bil (D) levels were assessed for the liver function. Treatments with (+) and without (−) acetaminophen or PM extracts are indicated on the abscissa. Each value represents the mean ± S.E. The number of experimental mice used is given in the parentheses. Each value represents the mean ± S.E. Differences where \(p < 0.05\) (•) or \(p < 0.01\) (•) and those where \(p < 0.001\) (••) were considered significant when compared with the acetaminophen-treated (10 mM, shaded bar) and corresponding PM (without acetaminophen) groups, respectively.
Mice were orally pretreated with hot-water PM extracts (lower dose: 20 mg/0.2 ml/mouse, higher dose: 340 mg/0.2 ml/mouse) twice a day for 10 consecutive days, while control animals were similarly treated with distilled water (2 × 0.2 ml per day). On day (final) 10, acetaminophen (500 mg/kg) was injected intraperitoneally in mice 2 hr after the last oral administration of PM extracts. Liver tissue was removed from mice (n = 3 in each group) under ether anesthesia 4 hr after acetaminophen treatment.

The present hot-water-extracted PM not only prevented cell damage in serum-free culture media but also significantly attenuated acetaminophen-induced hepatotoxicity in the cultured hepatocytes. The significant preventive effect of hot-water-extracted PM in vivo was also observed on the acetaminophen-induced hepatotoxicity, however, only when extremely high dosage of PM extract (ca., 20 g/kg) was administered. In other words, the recommended dose of commercial PM products would not have significant benefit effect on hepatic failure. Acetaminophen was employed to induce hepatotoxicity in the present study because acetaminophen overdose induces fatal hepatic toxicities such as hepatic centrilobular necrosis. Acetaminophen-induced hepatotoxicity involves free radical species, such as N-acetyl-p-benzoquinomine, which behave as highly reactive metabolites strongly bound to proteins. As such, the PM extract might have attenuated acetaminophen-induced hepatotoxicity via the antioxidation mechanism. In fact, anthraquinone, which is one of the PM components, exhibits antioxidative properties that enhance the hepatic mitochondrial glutathione status. Previous reports have indicated that the PM extract, which has been extracted by ethyl acetate, attenuates CCl₄-induced hepatotoxicity in mice. PM extracts isolated by organic solvents show higher antioxidant activity. Overall, our results in this study indicated that the hot-water-extracted PM, which is the conventional and popular PM preparation for consumption, exhibited non-injurious and limited beneficial effects on the liver function.

In conclusion, the hot-water-extracted PM in the present study showed protective effects against acetaminophen-induced toxicity in primary-cultured hepatocytes, and subchronic (10-day) daily intake of the PM extract did not induce any hepatotoxicity per se. In fact, attenuation of acetaminophen-induced hepatotoxicity was established with our PM extract pretreatment, albeit the in vivo beneficial effect was obtained by the extremely high dosing.
